

BABY COIN

Transparent Fixed-Supply Token Whitepaper

Version 1.0 | September 2026

BNB Smart Chain | Symbol: BABY | Fixed Supply: 21,000,000

Contract	0x0e5f7CF1641d029Cfb0c11bc1f485d33d26104B0
Decimals	18
Official Assets	github.com/mohsenorak-dotcom/baby-coin-assets
Source Status	Published and verified on BscScan

Public technical disclosure - not investment advice

Executive Snapshot

Network	BNB Smart Chain
Token Standard	ERC-20-compatible / BEP-20 ecosystem
Total Supply	21,000,000 BABY - fixed
Taxes	0% buy / 0% sell / 0% transfer in token logic
Administrative Controls	No owner-only mint, tax, blacklist, pause, or wallet-limit functions
Upgradeability	None in the deployed token contract

Reading rule: For technical facts, the deployed contract and observable on-chain transactions take priority over promotional claims or third-party displays.

The following core whitepaper is intentionally organized as exactly 100 numbered statements so every material claim can be referenced unambiguously.

1. Project Overview

- 001.** BABY COIN (BABY) is a fixed-supply digital token deployed on BNB Smart Chain and designed around simplicity, public verifiability, and predictable transfer behavior.
- 002.** The project uses an ERC-20-compatible token interface on BNB Smart Chain so standard wallets, explorers, decentralized exchanges, and smart-contract tools can interact with BABY.
- 003.** BABY COIN does not promise a guaranteed financial return, fixed price, yield, dividend, or redemption value, and this whitepaper must not be read as such a promise.
- 004.** The project objective is to keep the base token contract intentionally minimal so users can understand the core rules without hidden transfer mechanics or complex administrative logic.
- 005.** The on-chain token name is BABY COIN and the on-chain symbol is BABY.
- 006.** The deployed contract address is 0x0e5f7CF1641d029Cfb0c11bc1f485d33d26104B0 on BNB Smart Chain.
- 007.** The token uses 18 decimals, which is the conventional precision used by many ERC-20-compatible assets.
- 008.** The total supply is permanently defined in the deployed contract as 21,000,000 BABY, represented internally as $21,000,000 \times 10^{18}$ base units.
- 009.** The project treats the blockchain contract, verified source code, and transaction history as the primary source of truth whenever marketing material or third-party interfaces differ.
- 010.** This document is Version 1.0 of the public BABY COIN whitepaper and is intended to describe the token honestly without implying features that are not present in the deployed code.

2. Design Principles

- 011.** Simplicity is a core design principle: the token contract focuses on balances, transfers, allowances, approvals, and transferFrom functionality rather than layered tokenomics.
- 012.** Transparency is a core design principle: critical parameters such as name, symbol, decimals, total supply, and logo reference are exposed as public constants.
- 013.** Predictability is a core design principle: the contract does not dynamically change fees, supply, wallet limits, or trading conditions after deployment.

- 014.** Neutral transfer behavior is a core design principle: the same token transfer rules apply regardless of whether a transfer is wallet-to-wallet or routed through a decentralized exchange.
- 015.** The contract does not contain buy-tax, sell-tax, transfer-tax, reflection, redistribution, rebasing, or automatic-liquidity fee logic.
- 016.** The contract does not include blacklist or whitelist functions that can selectively prevent specific addresses from transferring BABY.
- 017.** The contract does not include max-wallet or max-transaction restrictions, meaning the token contract itself does not impose artificial holding or transfer ceilings.
- 018.** The contract does not include a pause switch, emergency freeze mechanism, or trading-enable flag that can be used to halt ordinary token transfers.
- 019.** The contract does not include proxy or upgradeability logic, so the deployed bytecode cannot be replaced through an upgrade administrator built into the token.
- 020.** External websites, wallet interfaces, exchange listings, and metadata services are convenience layers only; none of them can modify the immutable rules already deployed in the BABY token contract.

3. Token Supply and Genesis Distribution

- 021.** The BABY supply is fixed at 21,000,000 tokens and the deployed contract contains no public or privileged mint function capable of increasing that supply.
- 022.** All 21,000,000 BABY were created at deployment and credited to the deployer address by the constructor, with a Transfer event emitted from the zero address.
- 023.** Because the entire supply begins at the deployer address, subsequent allocation to liquidity, community wallets, partners, users, or other addresses is visible through normal on-chain transfers.
- 024.** The contract does not contain an embedded vesting schedule, allocation table, treasury module, or automatic distribution mechanism.
- 025.** Any future allocation plan must therefore be evaluated using actual wallet addresses and transaction records rather than relying solely on statements in promotional material.
- 026.** The contract has no inflation schedule, block-based emissions, staking emissions, mining rewards, or periodic token creation.
- 027.** The contract has no rebase mechanism, so user balances do not automatically expand or contract as a result of supply-adjustment logic.
- 028.** The contract has no built-in burn function; holders may still irreversibly reduce accessible supply by sending tokens to an unrecoverable address, but that is not a privileged protocol feature.
- 029.** The displayed circulating supply on third-party services may differ from total supply because those services may exclude locked, burned, liquidity, or inactive balances according to their own methodologies.
- 030.** Users should always distinguish total supply, circulating supply, liquidity inventory, and holder balances because each metric answers a different economic question.

4. Smart Contract Behavior

- 031.** The balanceOf function returns the recorded BABY balance for a specified address.
- 032.** The transfer function moves BABY from the caller to a non-zero recipient when the caller has a sufficient balance.

- 033.** The approve function allows a holder to authorize a non-zero spender to use a specified allowance on the holder's behalf.
- 034.** The allowance function exposes the remaining approved spending amount between an owner address and a spender address.
- 035.** The transferFrom function moves BABY from an approved address when both the source balance and spender allowance are sufficient.
- 036.** Successful transfers emit the standard Transfer event, enabling explorers, wallets, indexers, and analytics tools to track token movements.
- 037.** Approvals and allowance changes emit the standard Approval event, allowing third-party interfaces to track delegated spending permissions.
- 038.** The contract rejects transfers to the zero address rather than treating the zero address as a normal recipient.
- 039.** The contract contains no router address, pair address, DEX-specific restriction, anti-bot callback, or external oracle dependency in its transfer path.
- 040.** Because ordinary transfers do not make external contract calls, the token's core transfer path is comparatively small and easier to reason about than feature-heavy fee tokens.

5. Control, Governance, and Administrative Power

- 041.** The deployed BABY contract does not expose an owner variable or owner-only administrative function in the token logic described by the verified source.
- 042.** There is no contract-level function for an administrator to change the token name, symbol, decimals, or total supply after deployment.
- 043.** There is no contract-level function for an administrator to introduce a new transfer tax after deployment.
- 044.** There is no contract-level function for an administrator to blacklist a holder or confiscate a holder's balance.
- 045.** There is no contract-level function for an administrator to pause transfers globally.
- 046.** There is no contract-level function for an administrator to set maximum-wallet or maximum-transaction limits.
- 047.** There is no contract-level function for an administrator to mint additional BABY after the initial deployment.
- 048.** Because the contract is not upgradeable, future project features should be delivered through separate contracts or applications rather than by silently altering the deployed BABY token logic.
- 049.** Off-chain project decisions, website administration, social-media accounts, liquidity management, and treasury management remain separate from the immutable token contract and may still involve human control.
- 050.** Users should distinguish “no token-contract admin powers” from “no project operational control,” because liquidity wallets, websites, listings, and communication channels can still be managed off-chain.

6. Trading, Market Formation, and Liquidity

- 051.** BABY is intended to be transferable and may be traded through compatible decentralized exchanges on BNB Smart Chain when a market pair and sufficient liquidity exist.

- 052.** The project's intended primary decentralized market is a BABY/WBNB pair on PancakeSwap, but a pair should not be considered active until it is verifiably created on-chain.
- 053.** The BABY token contract itself does not create liquidity, determine market price, guarantee market depth, or guarantee the ability to sell at a desired price.
- 054.** Initial token price is determined by the ratio of assets supplied to a liquidity pool and can change immediately as market participants trade.
- 055.** Low-liquidity markets can experience large price movements, high slippage, failed quotes, and rapid changes in obtainable execution price.
- 056.** Liquidity-provider positions are separate on-chain assets and are not automatically locked by the BABY token contract.
- 057.** If liquidity is locked, the project should publish the locker, chain, lock duration, LP position or token identifier, and verifiable transaction references so users can independently confirm the claim.
- 058.** Any targeted liquidity amount mentioned before funding occurs should be treated as a plan rather than completed liquidity until the corresponding on-chain transactions exist.
- 059.** The project does not promise price support, buybacks, market-making performance, minimum market capitalization, or guaranteed exchange listing.
- 060.** Users should verify the exact BABY contract address before every trade because identical or similar token names and symbols can be created by unrelated third parties.

7. Metadata, Branding, and Wallet Display

- 061.** The contract exposes a logoURI constant pointing to the project's public GitHub-hosted BABY COIN logo.
- 062.** The current logo reference is <https://raw.githubusercontent.com/mohsenorak-dotcom/baby-coin-assets/main/Logo.PNG>.
- 063.** The official public asset repository is <https://github.com/mohsenorak-dotcom/baby-coin-assets> and should be used as a reference point for project branding assets.
- 064.** Wallets are not required by the ERC-20 or BEP-20 standards to read logoURI, so the presence of the on-chain URL does not guarantee that a wallet will automatically display the image.
- 065.** MetaMask and other wallets may use their own token-detection systems, metadata registries, caches, or third-party providers to determine whether a logo and market information appear.
- 066.** BscScan, decentralized-exchange analytics services, portfolio applications, and wallet providers may each require separate metadata submissions and may apply their own review criteria.
- 067.** A missing logo in a wallet does not change token ownership, balances, transferability, or contract validity.
- 068.** A displayed logo is not proof that a token is safe, endorsed, audited, or officially affiliated with a wallet provider.
- 069.** The contract address is the canonical identifier of BABY; visual branding, name, symbol, and logos should be treated as secondary identifiers.
- 070.** Any future website, documentation page, or social account presented as official should publish the same contract address so users can cross-check project identity.

8. Security and Operational Risk

- 071.** The source code has been published and verified on BscScan, which allows users to compare human-readable source with deployed contract bytecode through the explorer's verification process.
- 072.** Verified source code improves transparency but is not equivalent to an independent security audit, formal verification, or guarantee that all risks have been identified.
- 073.** This whitepaper does not claim that BABY has completed an independent third-party smart-contract audit unless such an audit is separately published with a verifiable report.
- 074.** Private-key security remains critical because anyone controlling a wallet's private key or recovery phrase can control the BABY held by that wallet.
- 075.** Users should never disclose seed phrases, private keys, or wallet-recovery information to project representatives, support accounts, websites, or smart-contract interfaces.
- 076.** Token approvals can expose holders to spender risk, so users should review allowances and revoke approvals that are no longer required.
- 077.** Phishing websites can imitate legitimate wallet, explorer, or exchange interfaces; users should verify domains and contract addresses before signing messages or transactions.
- 078.** Smart-contract simplicity reduces some categories of logic risk but does not eliminate blockchain, wallet, bridge, exchange, liquidity, front-end, key-management, or market risk.
- 079.** BNB Smart Chain network congestion, validator conditions, RPC availability, wallet software, or third-party service outages can temporarily affect access or transaction submission.
- 080.** Every user is responsible for understanding transaction details, gas fees, slippage, approvals, and counterparty or protocol risks before interacting with BABY or related applications.

9. Development and Transparency Roadmap

- 081.** Phase 1 focuses on the foundational token: deployment, source-code publication, BscScan verification, and publication of official branding assets.
- 082.** Phase 2 focuses on transparent market infrastructure, including creation of a BABY/WBNB liquidity pool when the project is ready to fund and publicly document that pool.
- 083.** If a liquidity-lock commitment is made, Phase 2 also includes publishing verifiable lock evidence rather than relying on screenshots or unverifiable claims.
- 084.** Phase 3 focuses on improving token discoverability across wallet metadata systems and blockchain explorers, subject to each third-party provider's acceptance rules.
- 085.** Phase 4 focuses on market-data indexing by compatible decentralized-exchange analytics platforms after a valid pair and trading activity exist.
- 086.** Phase 5 may include applications to larger token directories or market-data services when their eligibility requirements are met.
- 087.** The project may add a dedicated website and additional public documentation, but those resources will remain informational and will not alter the immutable token contract.
- 088.** Future ecosystem utilities, if any, should be documented before launch with clear user value, separate contract addresses where applicable, and explicit security assumptions.
- 089.** Roadmap items are objectives rather than guarantees; timing may change because third-party reviews, technical dependencies, liquidity decisions, market conditions, or compliance requirements are outside the token contract.

090. Completed milestones should be evidenced by public URLs, contract addresses, transaction hashes, or repository history whenever such evidence is technically available.

10. Legal, Risk, and Final Disclosures

091. BABY is a blockchain token and its legal or regulatory classification can differ by jurisdiction; this whitepaper does not determine that classification for any reader.

092. This document is informational and technical in nature and does not constitute investment, legal, tax, accounting, or financial advice.

093. Nothing in this whitepaper is an offer, promise, or guarantee of profit, appreciation, liquidity, listing, exchange acceptance, or future utility.

094. Cryptographic assets can lose part or all of their market value, and holders should only assume risks they independently understand and can afford to bear.

095. Users are responsible for determining whether acquiring, holding, transferring, or trading BABY is lawful in their jurisdiction and compatible with applicable restrictions.

096. Third-party services such as wallets, exchanges, explorers, market-data sites, liquidity lockers, and analytics providers operate independently and are not controlled by the BABY token contract.

097. References to third-party brands or platforms describe intended or actual interoperability and do not imply sponsorship, endorsement, partnership, or approval unless separately confirmed by that third party.

098. If any statement in promotional material conflicts with the deployed contract, verified source code, or observable on-chain transactions, the on-chain evidence should take priority for technical facts.

099. The project should update future versions of this whitepaper when material operational facts change, while preserving historical versions so readers can see what was represented at each stage.

100. BABY COIN is presented as a transparent fixed-supply token project whose core commitment is straightforward: publish the rules, avoid hidden token mechanics, and let users verify material claims on-chain.
